Abstract

PREDICTORS ASSOCIATED WITH 30-DAY READMISSION AMONG A COHORT OF ADULT CONGENITAL HEART DISEASE PATIENTS, MEDICAID CLAIMS DATA 2010-2013

By Giancarlo Licitra

Purpose:

Advancements in medical technology and treatment of CHD has led to improved survival. Adults with CHD (ACHD) have been largely understudied, especially with respect to hospital readmissions - a quality indicator commonly used to assess healthcare utilization. This study aims to identify common diagnoses at index admission associated with readmissions within 30-days of a cardiac-related hospital admission among ACHD patients. We also analyze socio-contextual factors associated with 30-day readmission including race, sex, and distance from patient zip code to a facility providing specialized cardiology care.

Methods:

This study is a retrospective cohort design analyzing Georgia Medicaid claims data, 2010-2013. The sample consists of ACHD patients aged 20-64 years, covered under Medicaid and with at least one of 55 ICD-9-CM CHD diagnostic codes on their encounter claim (n=1,697). To assess travel distance to specialized healthcare facilities, we conducted adjusted Cox-proportional models and reported hazard ratios with corresponding 95% CI's.

Results:

Of the 1,697 patients included in the analysis, about 22% had a 30-day hospital readmission. The remaining 78% had no recorded hospital readmissions within 30 days. Readmission was higher for those at initial admission with comorbid congestive heart failure (CHF) non-hypertensive (13% higher in readmitted patients compared to non-readmitted patients), fluid and electrolyte disease (15% higher), and diabetes mellitus (DM) with complications (~7% higher). Readmission was also higher for black patients compared to white (~6% higher). After adjustment for potential confounding variables, there was no significant increase in hazard found for greater distance between patient's resident zip code and healthcare facilities providing cardiology care.

Conclusion:

Specific comorbid diagnoses at index admission and black race identify subpopulations at increased risk for 30-day hospital readmission. Increased attention to comorbid diagnoses during initial hospital stay may reduce 30-day hospital readmission rates and improve health outcomes for the ACHD population.

Acknowledgements

I would like to first thank my thesis committee, Dr. Carol Hogue, Cheryl Raskind-Hood, and Trenton Hoffman for their guidance, mentorship and support throughout this entire process. Trenton was especially helpful in solving the logic puzzle of Medicaid claims data. I learned many valuable concepts and lessons from my thesis committee through this process and I am forever grateful.

I'd also like to thank Dr. Wendy Book for her mentorship and clinical expertise. I am lucky enough to work with Dr. Book in the clinic every week which has given me insight into the clinical realities for adults with CHDs. Working in the Emory ACHD clinic was the inspiration for this thesis and the patient interactions I experienced in the clinic provided me with motivation to work thoroughly towards finishing this project.

I would like to thank my family and friends, especially my girlfriend, Taylor Sauban, and my roommate, Taylor Snipes, for encouraging me through this process. I want to also thank my family, Carmelo and Doreen Licitra, Brian and Melina Hernandez, and Joshua and Alyssa Rose for providing continued support, love and encouragement not only for this project but throughout my life. I also want to thank my good friend Joe Gerth for his support, helping me work through coding issues and data questions. I could not have produced this thesis without the support of everyone listed above.

CHAPTER I: BACKGROUND

Congenital Heart Defect (CHD)

A congenital heart defect (CHD) is a structural anomaly of the heart presenting at birth differing in severity and defect type. CHDs are the most common type of birth defect. About one in four babies born with a heart defect has a critical CHD resulting in surgery or other procedures early in life [1]. The etiology of a CHD varies and is largely unknown. Approximately 15% of CHD cases are linked to a known cause, and it is currently understood that chromosomal aneuploidies are associated with malformation syndromes that compromise heart structure leading to a CHD diagnosis [2]. Around 2% of all congenital cases are associated with environmental factors and exposures such as maternal diabetes, phenylketonuria, maternal obesity, alcohol use, rubella infection, febrile illness and maternal exposure to certain drugs including thalidomide and retinoic acid [2]. Existing literature also suggests possible interaction between genetic aneuploidies and environmental exposures contributing to the presentation of CHDs [2].

Each year, around 40,000 babies in the United States are born with a CHD [3]. More than 90% of infants born with a CHD survive into adulthood, and the number of adults now living with CHD is greater than the number of children with a CHD [3]. It is estimated that 8 to 10 per 1000 live births in the United States have a diagnosis of a heart defect [4]. Diagnoses typically occur before or at the time of birth; however, some diagnoses occur much later in life. It is not uncommon for cases to go undiagnosed for some time, giving rise to the possibility that the prevalence of CHD in the population is underestimated [2].

Across the existing scientific literature, a CHD varies in definition and categorization. Mitchell and colleagues (1971) define a CHD as, “a gross structural abnormality of the heart or

intrathoracic great vessels that is actually or potentially of functional significance”; arrhythmias unrelated to heart structure and abnormalities of systemic veins are not included using this definition [5]. Variations in definitions and interpretations of CHDs highlight an issue with consistency not only with epidemiological studies, but also with clinical diagnoses in the healthcare setting. Typically, CHDs are classified by severity. For instance, a severe CHD classified by the Marelli scheme reflects patients with the highest probability for cyanosis or surgical intervention early in life [6]. Severe defects include atrioventricular canal defect (AVCD), tetralogy of Fallot (TOF), univentricular heart, transposition complex (complete or congenitally corrected transposition), truncus arteriosus and hypoplastic left heart syndrome (HLHS) [6]. Using a modified version of the Marelli scheme, non-severe CHDs can be further classified as shunt, valve, shunt + valve, and other (Appendix A). The scheme developed by Connelly and colleagues (1998) also classifies CHDs by severity; this scheme is based on how often patients should be seen at specialized CHD healthcare centers [7].

Advancements in medical technology and treatment have led to an overall improvement in survival of patients with CHDs. The median age at death for patients with a CHD has increased more than 20 years since 1987 [4]. From 1985-2000, the median age of those alive with a severe CHD increased from 11 to 17 years and is expected to continue to increase between 2000 and 2020 [4]. Despite progresses in survival, CHD remains the most common cause of infant death associated with birth defects [8]. Individuals living with a CHD, especially adults, require continuous, specialized healthcare and surveillance over their lifespan.

30-Day Hospital Readmission

A 30-day readmission is defined as a hospital admission within 30-days after discharge corresponding to the index hospitalization. Scheduled procedures, planned admissions and

emergency room visits without a resulting hospitalization are typically excluded [9]. Typically, patients must be alive during the follow-up time after the index admission discharge. If patients are transferred to other acute care facilities such as rehab and other long-term care facilities, they are typically excluded [10]. Hospital readmission is a quality indicator commonly used to assess healthcare utilization [11]. About 20% of Medicare patients are readmitted within 30-days of discharge [9]. Costs of these unplanned admissions are estimated to be more than \$17 billion per year [9]. In response, the Affordable Care Act (ACA) established the Hospital Readmissions Reduction Program (HRRP) providing financial incentives for hospitals to reduce preventable readmissions. The HRRP program targets Medicare beneficiaries and took effect in 2013. Targeted readmission diagnoses for the HRRP include acute myocardial infarction (AMI), congestive heart failure (CHF), and pneumonia (PNA) [12]. In 2015, chronic obstructive pulmonary disease (COPD) and hip/knee replacements were added to the list of targeted readmission diagnoses [12].

Implementation of the HRRP has spurred research interest in risk factors for hospital readmission. Fingar and colleagues (2006) investigated conditions at index admission associated with higher rates of readmission among the Medicare population. The diagnosis associated with the highest rate of readmission was CHF, non-hypertensive, followed by schizophrenia and other psychotic disorders, respiratory failure/insufficiency/arrest, diabetes mellitus (DM) with complications, acute renal failure, and COPD [12]. Social risk factors for increased 30-day readmission include older age, non-white, low socio-economic status, lack of social support, being unmarried, and risk behaviors such as illicit drug use, alcoholism, and poor medical adherence [13]. Numerous epidemiological studies have found that lack of early 7-day physician follow-up post-index admission discharge is associated with increased readmission rates

compared to no physician follow-up. This association is primarily seen for patients with an index diagnosis of either CHF [14] [15] and/or a non-ST segment elevated myocardial infarction (NSTEMI) [16]. Mixed evidence for this association exists analyzing 30-day readmission for all index diagnoses [17].

In response to the HRRP, hospitals have created initiatives designed to decrease readmission rates. These initiatives have targeted the transition from inpatient care to outpatient care following index admission discharge with the understanding that the lack of a 7-day physician follow-up is a key risk factor for hospital readmission. Initiatives involving home-visiting programs, multidisciplinary heart failure (HF) clinic interventions, and structured telephone support have shown success in decreasing hospital readmission rates and overall mortality for patients with a CHF diagnosis [18]. The Alberta Cardiac Access initiative was created to improve access to specialized HF clinics and has resulted in a substantial decrease in readmission and mortality within 30-days of discharge [19]. Kamermayer and colleagues (2017) summarize these findings in their review stating, “even though not all readmissions are preventable, multicomponent discharge interventions and a team-based approach are more likely to reduce readmissions and improve outcomes in recently discharged medical and surgical patients” [20].

Congenital Heart Defects (CHD) and 30-Day Readmission

Cedars and colleagues (2016) analyzed one-year readmission rates in an ACHD population (n=64,420) using state inpatient data from Arkansas, California, Florida, Hawaii, Nebraska and New York [21]. They found 39% of CHD patients experienced a one-year readmission and reported that predictors for readmission were lesion specific. Lesions associated with higher readmission included Eisenmenger syndrome or cyanosis, single ventricle

physiology, and conotruncal abnormality. Diagnoses at index admission associated with increased readmission rates, ranked highest to lowest, were CHF, arrhythmia, congenital heart disease, sepsis and nonspecific chest pain. Comorbidities associated with increased readmissions include chronic kidney disease (CKD) and DM with complications [21]. Patients with readmissions were more likely to be women, slightly older, had longer index admission stays, and were less likely to have had a major operation at index admission [21].

In another study by Islam and colleagues (2016), of hospital readmission in a Canadian CHD population (n=65,252, all ages), investigators found that regardless of age, 7.6% of patients were readmitted within one month [22]. Older, male patients with higher Charleston Comorbidity Index (CCI) scores were more likely to have higher rates of one-month readmission. Among adults, CHF, atrial fibrillation and flutter, non-rheumatic aortic valve disorder, and ischemic heart disease (IHD) were the most common non-CHD diagnoses at the time of readmission among patients with a 30-day readmission [22]. At the time of index admission, the most common diagnoses were CHF, infective endocarditis, and IHD. The most common primary CHD diagnoses at index admissions for adults were grouped by severity. The group including TOF, transposition of the great arteries, truncus arteriosus, and total anomalous pulmonary venous connection had the highest percentage of one-month readmission (7.4%) followed by a group containing hypoplastic left heart syndrome, univentricular heart, and tricuspid atresia (6.9%) [22]. The last grouping with the lowest percentage of 30-day readmissions included atrioventricular septal defect, ventricular septal defect (VSD) and atrial septal defect (ASD) (6.4%) [22].

A study in a Swiss university hospital of 996 non-adult CHD patients (ages 0-18) analyzed 30-day readmission focusing on demographic and existing conditions [23]. Patients

living farther from the hospital of admission had a higher readmission risk; however, the study indicates this finding may be confounded by CHD severity. Patients living farther from the hospital are more likely to have a severe CHD, motivating travel to a specialized clinic. Patients with severe CHDs are also likely to have higher readmission rates due to their existing condition suggesting a potential confounding bias. Patients hospitalized for surgery had lower readmission rates, similar to the finding for adults in the previously mentioned 2016 study by Cedars and colleagues. Contrary to existing literature however, longer length of stay at index admission was associated with a lower readmission risk. Authors believe pediatricians may have been reluctant to discharge a child with a CHD, thereby artificially increasing the length of stay [23].

Travel Distance

Social determinants and barriers to health have an influence on hospital readmission risk in both adult and pediatric populations [24]. According to Lax and colleagues (2017), “Social determinants of health include the conditions in which people are born, live and work and how they are influenced by the distribution of money, power and resources” [25]. Geographic barriers to healthcare access are of interest for research, especially for rural populations. Patients with CHDs living in rural areas may have to travel long distances to receive specialized cardiology or hospital care. If patients have a farther distance to travel for follow-up post admission, they may be less likely to follow-up, thus increasing their risk of readmission [20, 26].

In the previously described Swiss study of pediatric CHD patients, Chave and colleagues (2017) analyzed the association between patient distance from the admitting Swiss university hospital and readmission [23]. Distance from the hospital was categorized in three categories: patients from the same canton as the hospital, patients from the four neighboring cantons, and other cantons. Pediatric patients living farther from the hospital (other cantons) of admission had

a significantly higher readmission risk [23]. To our knowledge, no study other than the one just described with a pediatric population assesses travel distance and readmission risk among CHD patients [23]. A study in Virginia conducted by Turrentine and colleagues (2017) of 5,425 patients, ages 18 and above, admitted for general surgery found each increase of 10 minutes in the time a patient must travel in a car to the nearest hospital was associated with a 9% increase in the probability of readmission status post-surgery [26]. Variable adjustments included patient demographic characteristics, pre-operative comorbidities, laboratory values, and post- and pre-surgical complications [26]. In a study conducted by Piette and Moos (1996) analyzing the association between travel distance and patient mortality within a year after discharge, investigators studied 4,637 male patients admitted for myocardial infarction, ages 18 and up. They found that patients living more than 20 miles from their admitting hospital were significantly more likely to die within the first-year post-discharge [27].

Medicaid Claims

Insurance claims provide a rich source of data for analyzing healthcare utilization. While claims data, specifically Medicaid, has a high congruence with electronic medical records (eMR) especially for screening measures and medical procedures, poor agreement has been revealed for some measures including body mass index (BMI) [28]. Medicaid claims data however, are dependent on the quality of information received by the providing healthcare source. Quality is also dependent on the accuracy of the compiled claims records created by Medicaid. Diagnosis codes on Medicaid claims may include diagnoses and procedures associated with higher cost billing conditions and may not accurately reflect the patient's actual health condition [29]. For example, applying higher rate cost billing procedures to CHD claims tends to overestimate the severity of the patient's condition [21]. It is important also to note that the population eligible for

Medicaid is often dependent on fixed income and does not accurately represent patients without insurance coverage or patients using other public or private insurers. Studies utilizing Medicaid claims data may lack generalizability to the entirety of the adult CHD population [30].

Converting medical claims data into a research database is difficult and requires a methodical approach. Tyree and colleagues (2006) identified four major challenges with using Medicaid data: conversion of claims into unique visits, identification of incomplete claims data, categorization of providers and locations of service, and selecting the most useful measures of utilization and expenditures [30]. Conversion of claims into unique visits is difficult without the use of chart review. Multiple lines of duplicate data on or around the date of the initial claim could represent a repeat visit or an adjustment to the original claim. One study analyzing readmission among Medicare beneficiaries decided to exclude all same-day claims and defined a readmission as any inpatient hospital-related claim within a 30-day period of the index discharge [31]. Multiple visits to the same provider on the same day are thought to be rare events, so these records are always treated as claim adjustments and typically are excluded from readmission analysis [30].

Jencks and colleagues (2009) utilized diagnosis related groups (DRG) to categorize types of inpatient visits in order to analyze 30-day readmission in a Medicare population [10]. Also found in Medicaid, DRGs categorize inpatient admissions based on diagnosis, complications and comorbidities [32]. DRGs are helpful for identifying non-hospital inpatient admissions such as transfers to long-term care facilities, rehabilitation, or other planned admissions. The Jencks et al. (2009) paper examined the DRGs most frequently used in all potential readmission claims. They individually examined each DRG to determine whether it was likely a planned admission or not. For example, a HF re-hospitalization was likely not planned compared to a hospitalization

for a stent placement. They found only about 10% of total readmissions (19 out of 100 DRG's) were thought to be planned [10].

To our knowledge, few studies have analyzed 30-day readmission in a Medicaid population compared to the popular and accessible Medicare populations. This is most likely because the HRRP is specific to Medicare populations, and thus, attracts research interest. Studies have shown readmission rates for the Medicare populations have decreased since the implementation of the HRRP [12]. The same cannot be said for the Medicaid population. Thirty-day readmission rates decreased for all payers between 2009 and 2013, except for Medicaid [12]. Medicare had higher readmission rates compared to all other payers, except for Medicaid in the years 2009-2013 [12]. This suggest trends in 30-day readmission rates differ by payer type. Assumptions about the effect of the HRRP on Medicare cannot be used when analyzing Medicaid data.

Georgia Medicaid

The Medicaid population in Georgia reflects the eligibility criteria for enrollment. Georgia Medicaid receives federal and state funding to provide care for children under 19 years of age, pregnant women, families with dependent children under 19 years of age, and people who are aged, blind and/or disabled and whose income is insufficient to meet the cost of necessary medical services [33]. U.S citizens or qualified immigrants are eligible, however; “non-qualified immigrants or undocumented immigrants may only be eligible for coverage of emergency medical services” [33]. To qualify for Medicaid as a disabled adult (ages 21 to 64), the person must receive benefits in the form of Supplemental Security Income (SSI). In addition, disabled persons living in a nursing home facility and having both limited assets and a low income qualify for Medicaid. Also, those who can stay at home with community care services to utilize regular

nursing care and personal services can apply for Medicaid benefits [34]. These criteria are more stringent than those in place to determine Medicaid eligibility for persons younger than 21. Further, there is a substantial waiting list for Medicaid coverage of blind and/or disabled individuals who do not also qualify for Medicare [35] [36].

Otherwise qualified individuals and families are eligible if their household income does not exceed \$653 per month [33]. Pregnant women can apply for Medicaid through their local county health department and receive Presumptive Eligibility (PE) Medicaid. This coverage begins immediately, but is temporary and does not cover inpatient hospital services and labor and delivery [33]. Complete eligibility determination may take up to 10 days. Women under the age of 65 diagnosed and in treatment for breast or cervical cancer are eligible for Medicaid if they have a low income, are uninsured, and are a qualifying Georgia resident [33]. Individuals who are aged 65 years or older, blind, or disabled are eligible for Georgia Medicaid coverage [33]. These individuals are not limited to Medicaid for health insurance coverage and may utilize private insurance or Medicare for insurance coverage [33].

CHAPTER II: METHODS

Hypotheses-

For Georgia Medicaid beneficiaries with a CHD diagnosis and at least one index cardiac hospital admission on a claim between 2010-2013, it is hypothesized that:

1. congestive heart failure (CHF) and arrhythmia are likely associated with higher rates of 30-day hospital readmission.
2. patients with a severe CHD classification will have higher rates of 30-day hospital readmission.
3. patients who live farther from facilities for cardiology follow-up will have higher rates of 30-day hospital readmission.

Study Design

This study is a retrospective cohort study analyzing secondary data obtained from Georgia Medicaid claims between 2010-2013. In collaboration with the CDC, this study is part of a larger pilot project conducted with Emory University whose aim is to develop a population-based surveillance system of Georgia adolescents and adults with CHD and to estimate the prevalence of disease with primary focus on those living within a five metro-Atlanta county area during 2008-2010 [21]. In addition, data used in the current study are also part of an expanded collaboration between Emory University and the CDC to look at CHDs across the life span, ages 1 to death, as well as extending the study timeframe to 2013. This thesis contributes to these larger projects by evaluating the 30-day hospital readmission rate among GA Medicaid beneficiaries during 2010-2013. All individuals in the sample were covered by Medicaid at some time during the 4-year period between 2010-2013.

Data used for the current thesis were obtained from Emory's population-based surveillance data repository that include Georgia Medicaid administrative claims from January 1, 2010 through December 31, 2013 for individuals with a CHD diagnosis. Inpatient Medicaid claims are used for this project, and these data were obtained from the Centers for Medicare and Medicaid Services (CMS) via Research Data Assistance Center (ResDAC), a CMS contractor that assists academic, government, non-profits and for-profits organizations acquire Medicaid and/or Medicare datasets [45].

Population

The study population consists of adult congenital heart defect (ACHD) patients, age 20-64 years. All ACHD patients have at least one of 55 ICD-9-CM CHD diagnostic codes on a Medicaid encounter claim (See Appendix A).

Data Management and IRB

The parent studies had approval from Emory University's Institutional Review Board (IRB#0000064051). To ensure data confidentiality, data were stored on a secure, private, Federal Information Security Management Act (FISMA)-compliant network storage drive at the Emory University, Rollins School of Public Health, IT Department server system, maintained only by authorized IT personnel and study researchers. Protected Health Information (PHI) was excluded from this dataset to maintain confidentiality and replaced with a unique identifier for each patient. Prior to analysis, all data were cleaned and de-duplicated.

Inclusion and Exclusion Criteria

Individuals included for analyses are ACHD patients aged 20-64 years. Index hospitalizations after November 30, 2013 are excluded from the study. Claims with a cardiac-related index admission are included for analyses, regardless of their diagnoses on subsequent

admissions. Non-cardiac index admissions are excluded. A cardiac admission is defined as having at least one ICD-9-CM Clinical Classification System (CCS) multi-level 1 code '7' of "diseases of the circulatory system" (Appendix D). For a patient to be eligible for inclusion, he/she must have continuous Medicaid coverage following a cardiac index admission until an outcome occurred, and so, an indicator was created for Medicaid eligibility during the same month of the claim and the next consecutive month. If a patient is not covered during this two-month period, the claim is excluded. The only possible caveat to this rule is for patients admitted on January 31st (30th during the 2012 leap year), who were then subsequently readmitted at the beginning of March within 30-days. Approximately 0.5% of patients were admitted on January 30th and 31st, and the percentage of those patients readmitted in March is considerably lower. Thus, controlling for this possibility is not necessary. Patients with a date of death listed before the end of the 30-days post-index admission are excluded (n=10).

Outcome Variables

The primary outcome is a hospital readmission within 30-days of an index hospital admission. A 30-day hospital readmission is defined as a hospital admission within 30-days after the discharge date corresponding to the index hospitalization. The other outcome is a patient who reaches 30-days after index admission without subsequent rehospitalization, thus is defined as being "not-readmitted." A 30-day readmission is calculated using the date of discharge of the index hospitalization claim and the following hospital admission date. Upon examination of Medicaid claims, there were instances of multiple claims on the same day or consecutive days indicating multiple claims filed for a single admission or possible billing adjustments. To avoid overestimation of readmissions, we combined encounter claims with overlapping or consecutive (abutting) date ranges. This was done for all encounters. Each patient contributed one period of

follow-up, and thus, could have a maximum of one readmission. If an included patient had any incidence of readmission during the follow-up period, the follow-up corresponding to the readmission is counted. Otherwise, for patients without a readmission, the first cardiac index admission is used to indicate start of follow-up, and follow-up time is counted up to 30-days as long as Medicaid coverage is continuous for this period.

Predictor Variables

Predictor variables assessed are severity of CHD diagnosis, age at index admission, sex, race, diagnoses at index admission, diagnoses at readmission, and travel distance from patient zip code to nearest ACHD provider (Appendix B), travel distance to Emory Clinic, and travel distance to the claim's listed NPI address. Severity of CHD at index admission is classified using a modified Marelli classification scheme (Appendix A). This scheme classifies disease as severe, shunt, valve, shunt + valve, and other. For our purposes, all non-severe diagnoses (shunt, valve, shunt + valve, and other) are collapsed into a "non-severe" category coded as '0' and dichotomized with severe diagnoses, coded as '1'. Age is calculated using integer values at the start of follow-up (index admission) and categorized into tertiles. These tertiles are ages 20-34 coded as '1', 35-54 coded as '2', and 55-64 coded as '3'. Sex is categorized as male coded as '1' or female coded as '0'. Race is reported using the same categorizations provided in the Medicaid dataset; white coded as '1', black coded as '2', and missing coded as 'missing'. Patients categorized as Asian are excluded from analysis due to low cell counts (n=13).

Diagnoses at index admission and diagnoses at readmission are categorized using the corresponding ICD-9-CM CCS multilevel 3 classifications (Appendix E). The top most frequent 13 comorbid diagnoses are identified and included in the analysis. If a patient has multiple occurrences of the same level 3 diagnosis classification used in a single claim, those duplicates

are grouped together and counted as one diagnosis. After initial analyses, three diagnosis categories were considered to assess confounding: CHF non-hypertensive, DM with and without complications, and fluid & electrolyte disease. Those with CHF non-hypertensive listed as a diagnosis are coded as '1' with those without CHF non-hypertensive are coded as '0'. Similarly, a dichotomous variable for those with fluid and electrolyte disease is coded as '1' for those with fluid and electrolyte disease and '0' for those without. There are two diagnosis categories listed for DM, DM with complications and without. Reference cell coding with dummy variables are created for diabetes, no diabetes as the referent group coded as '0', those with DM without complications coded as '1' for one dummy variable and another dummy variable coded for those with DM with complications coded as '1'.

Straight-line distances in miles are calculated using latitude-longitude coordinates. Distances from patient zip to Emory clinic, the nearest ACHD provider, and the listed NPI address are not distributed normally, thus they are log transformed. Reference cell dummy categories are created based on quartile cut-points along the log transformed distribution (min, 25th percentile, median, 75th percentile, and max). For distance to Emory clinic, the referent cut-point coded as '0' was <3.39 (29.7 miles), ≥ 3.39 -4.17 (64.7 miles) was coded as '1' for the first dummy variable, ≥ 4.17 -4.88 (131.6 miles) coded as '1' for the second dummy variable, and lastly ≥ 4.88 for the third. Distance to the nearest ACHD provider used the referent category <2.75 (15.6 miles) coded as '0', ≥ 2.75 -3.37(29.1 miles) is coded as '1' for the first dummy variable, ≥ 3.37 -3.97 (53.0 miles) coded as '1' for the second dummy variable, and lastly ≥ 3.97 for the third. Lastly, distance to the listed NPI address used the referent category <1.81 (6.1 miles) coded as '0', ≥ 1.81 -2.64 (14.0 miles) is coded as '1' for the first dummy variable, ≥ 2.64 -3.37 (29.1 miles) coded as '1' for the second dummy variable, and lastly ≥ 3.37 for the third.

Patients' resident zip codes are classified using the National Center for Health Statistics (NCHS) 2013 urban-rural classification scheme for counties. This scheme classifies counties as '1-Large central metro', '2-Large fringe metro', '3-Medium metro', '4-Small metro', '5-Micropolitan', and '6-Non-core'. Urban-rural levels 1-4 are collapsed into a 'Urban' classification coded as '0' [37]. Urban-rural levels 5 and 6 are collapsed into a 'Not-Urban' classification coded as '1'.

Directed Acyclic Graph (DAG)

A DAG was built to determine the potential associations between exposures and outcome, 30-day readmission. Diagnosis at index admission is used as the exposure and covariates considered for possible confounding in the DAG are CHD severity, age, race, distance to cardiology provider, smoking, comorbidities, and sex. Smoking is not included in the data set, thus, a possible source of unmeasured confounding (Supplementary Figure 7).

Statistical Analysis

All analyses were conducted using SAS 9.4 for Windows (Cary, NC). Frequencies and percentages are reported for categorical independent variables. Characteristics of the selected ACHD population are stratified by outcome of 30-day readmission. Bivariate analysis comparing race, sex, age at index admission, and severity of CHD diagnosis for the outcome measure were performed using a chi-square test of association at an alpha level of 0.05. Missing data on race are indicated as missing.

The association between CHD severity and 30-day hospital readmission is estimated using hazard ratios (HR) and 95% confidence intervals (95% CI) from a Cox-proportional hazards model. A similar model was run for the association between travel distance from patient zip code to nearest ACHD provider, Emory Clinic, and listed NPI address and 30-day

readmission. Another Cox-proportional model is used to test the association between selected diagnoses at index admission (CHF non-hypertensive, DM with no complications, and fluid & electrolyte disease) and 30-day readmission. The proportional hazards assumption is assessed for each predictor using $\log(-\log(\text{survival}))$ survival curves, goodness-of-fit testing, and time-dependent covariates. Assessment of confounding reviews all possible subsets of a gold standard model that includes adjustment for all covariates. Confounding is considered present if the corresponding subset's HR is greater than 10% of the gold standard model. Covariates considered for confounding include race, age, sex, CHD severity, and diagnoses at index admission including fluid & electrolyte disease, CHF non-hypertensive, and DM with and without complications. Models with race as a predictor are run without the observations containing missing race values. Kaplan-Meier curves are used to assess time until outcome stratified on CHD severity, race, age at index admission, sex, and travel distance from patient zip code to nearest CHD provider. Receiver-operator curves (ROC) are generated for specific diagnoses at index admission predicting 30-day readmission risk. These diagnoses are CHF non-hypertensive, fluid & electrolyte disease, and DM with and without complications.

CHAPTER III: MANUSCRIPT

PREDICTORS ASSOCIATED WITH 30-DAY READMISSION AMONG A COHORT OF ADULT CONGENITAL HEART DISEASE PATIENTS, MEDICAID CLAIMS DATA 2010-2013

By Giancarlo Licitra

Purpose:

Advancements in medical technology and treatment of CHD has led to improved survival. Adults with CHD (ACHD) have been largely understudied, especially with respect to hospital readmissions—a quality indicator commonly used to assess healthcare utilization. This study aims to identify common diagnoses at index admission associated with readmissions within 30-days of a cardiac-related hospital admission among ACHD patients. We also analyze socio-contextual factors associated with 30-day readmission including race, sex, and distance from patient zip code to a facility providing specialized cardiology care.

Methods:

This study is a retrospective cohort design analyzing Georgia Medicaid claims data, 2010-2013. The sample consists of ACHD patients aged 20-64 years, covered under Medicaid and with at least one of 55 ICD-9-CM CHD diagnostic codes on their encounter claim (n=1,697). To assess travel distance to specialized healthcare facilities, we conduct adjusted Cox-proportional models and report hazard ratios with corresponding 95% CI's.

Results:

Of the 1,697 patients included in the analysis, about 22% had a 30-day hospital readmission. The remaining 78% had no recorded hospital readmissions within 30 days. Readmission is higher for those with comorbid congestive heart failure (CHF) non-hypertensive (13% higher in readmitted patients compared to non-readmitted patients), fluid and electrolyte disease (15% higher), and diabetes mellitus (DM) with complications (~7% higher) at initial admission. Readmission is also higher for black patients compared to white (~6% higher). After adjusting for potential confounding variables, there is no significant increase in hazard found for greater distance between patient's resident zip code and healthcare facilities providing cardiology care.

Conclusion:

Specific comorbid diagnoses at index admission and black race identify subpopulations at increased risk for 30-day hospital readmission. Increased attention to comorbid diagnoses during initial hospital stay may reduce 30-day hospital readmission rates and improve health outcomes for the ACHD population.

Introduction

A congenital heart defect (CHD) is a structural anomaly of the heart presenting at birth differing in severity and defect type [1]. Each year, around 40,000 babies in the United States are born with a CHD [2]. More than 90% of infants born with a CHD survive into adulthood, and more adults than children now live with CHD [3]. Individuals living with a CHD require continuous and specialized healthcare and surveillance over their lifespan [1].

Hospital readmission is a quality indicator commonly used to assess healthcare utilization [4]. Adults with a CHD (ACHD) have been largely understudied, especially with respect to hospital readmissions. Previous literature describes the most common diagnoses associated with one-month readmission rates among Canadian ACHD patients. These include congestive heart failure (CHF), infective endocarditis, and ischemic heart disease (IHD) [5]. There is an association between decreased outpatient follow-up after a cardiac-related index hospital admission and increased 30-day hospital readmission rates [6], possibly related to the distance patients must travel after index admission to receive cardiology follow-up for their CHD [7]. To our knowledge, few studies have investigated 30-day hospital readmissions among the ACHD population in the United States.

This retrospective cohort study aims to identify common cardiac-related diagnoses at index admission associated with 30-day hospital readmissions among ACHD patients. We also analyze socio-contextual factors associated with higher hospital readmission rates including race, gender, and distance from patient zip code to Emory Clinic, the nearest ACHD provider and the listed NPI address. To our knowledge, this study is the first to investigate the association between 30-day hospital readmission and distance to facilities providing specialized cardiology care for an ACHD population in the United States.

Methods

Study Design

We conducted a retrospective cohort analysis of secondary data obtained from Georgia Medicaid claims between 2010-2013. In collaboration with the CDC, this study is part of a larger pilot project conducted with Emory University whose aim is to develop a population-based surveillance system of Georgia adolescents and adults with CHD and to estimate the prevalence of disease with primary focus on those living within a five metro-Atlanta county area during 2008-2010 [21]. In addition, data used in the current study are also part of an expanded collaboration between Emory University and the CDC to look at CHDs across the life span, ages 1 to death, and extending the study timeframe to 2013. This thesis contributes to these larger projects by evaluating the 30-day hospital readmission rate among GA Medicaid beneficiaries during 2010-2013. All individuals in the sample were covered by Medicaid at some time during the 4-year period between 2010-2013.

Data used for the current thesis are obtained from Emory's population-based surveillance data repository that include Georgia Medicaid administrative claims from January 1, 2010 through December 31, 2013 for individuals with a CHD diagnosis. Inpatient Medicaid claims are used for this project, and these data are obtained from the Centers for Medicare and Medicaid Services (CMS) via Research Data Assistance Center (ResDAC), a CMS contractor that assists academic, government, non-profits and for-profits organizations acquire Medicaid and/or Medicare datasets [45].

Population

AChD patients, age 20-64 years, with at least one of 55 ICD-9-CM CHD diagnostic codes on a Medicaid encounter claim in Georgia (See Appendix A).

We define a cardiac admission as having at least one ICD-9-CM Clinical Classification System (CCS) multi-level 1 code ‘7’ of “diseases of the circulatory system” (Appendix D). We created an indicator for Medicaid eligibility during the same month of the claim and the next consecutive month to assure that the patient had continuous Medicaid coverage following a cardiac index admission for at least 30-days. We include claims with a cardiac-related index admission, regardless of their diagnoses on subsequent admissions.

Exclusion Criteria

We exclude index hospitalizations after November 30, 2013, non-cardiac index admissions, and patients not continuously covered for the requisite two-month period. We also exclude patients who died before the end of the 30-days post-index admission (n=10). There are not enough Asians (n=13) to be included for analyses, thus, only whites and blacks are included in the dataset.

Predictor Variables

Predictors assessed are severity of CHD diagnosis, age, sex, race, diagnoses at index admission, diagnoses at readmission, and travel distance from patient’s resident zip code to a cardiology provider. We classify severity of CHD severity at index admission using a modified Marelli classification scheme (Appendix A). We collapsed all non-severe diagnoses (shunt, valve, shunt + valve, and other) into a “non-severe” category. We categorized integer age values at the index admission into tertiles.

Diagnoses at index admission and diagnoses at readmission are categorized using the corresponding ICD-9-CM CCS multi-level 3 classifications (Appendix E). The top 13 most frequent comorbid diagnoses are identified and included in the analysis. If a patient has multiple occurrences of the same level 3 diagnosis classification used in a single claim, those duplicates

are grouped together and counted as one diagnosis. After initial analyses, three diagnosis categories were considered for confounding assessment; CHF non-hypertensive, DM with and without complications, and fluid & electrolyte disease.

Straight-line distances in miles are calculated using latitude-longitude coordinates. Distances from patient zip to Emory clinic, the nearest ACHD provider, and the listed NPI address were not distributed normally, thus they are log transformed. Reference cell dummy categories are created based off quartile cut points (25th percentile, median, 75th percentile) along the log transformed distribution. Patients zip codes are also classified using the National Center for Health Statistics (NCHS) 2013 urban-rural classification scheme for counties.

Statistical Analysis

All analyses are conducted using SAS 9.4 for Windows (Cary, NC). Frequencies and percentages are reported for categorical independent variables. Characteristics of the selected ACHD population are stratified by outcome of 30-day readmission. Bivariate analysis comparing race, sex, age at index admission, and severity of CHD diagnosis for the outcome measure were performed using a chi-square test of association at an alpha level of 0.05. Claims with missing data on diagnoses were excluded. Missing data on race, gender and patient zip codes were indicated as missing.

The association between CHD severity and 30-day hospital readmission is estimated using hazard ratios (HR) and 95% confidence intervals (95% CI) from a Cox-proportional hazards model. A similar model is used for assessing the association between travel distances from patient zip code to cardiology healthcare facilities. Another Cox-proportional model is used to test the association between selected diagnoses at index admission (CHF non-hypertensive, DM with no complications, and fluid & electrolyte disease) and 30-day readmission. The

proportional hazards assumption is tested for each predictor using log(-log(survival)) survival curves, goodness-of-fit testing, and time-dependent covariates. Confounding assessment is reviewed by all possible subsets of a gold standard model and considered present if the corresponding subset's HR was greater than 10% of the gold standard model. All covariates listed above are considered for confounding. Models with race as a predictor were run without the observations containing missing race values. Kaplan-Meier curves assess time until outcome stratifying on CHD severity, race, age at index admission, sex, and travel distance from patient zip code to nearest CHD provider. Receiver-operator curves (ROC) are generated for specific diagnoses at index admission predicting 30-day readmission risk. These diagnoses include CHF non-hypertensive, fluid & electrolyte disease, and DM with and without complications.

Results

Of the 1,697 patients in the analysis, most are female and white with about 22% missing data on race (Table 1). Overall, about 23% have a severe CHD, and about 22% had a 30-day hospital readmission. The remaining 78% had no recorded 30-day hospital readmission.

Cardiac-related index admission diagnosis categories associated with 30-day hospital readmission include CHF non-hypertensive, fluid & electrolyte disease, and DM with complications. Readmission is higher for those at initial admission with comorbid CHF non-hypertensive (13% higher in readmitted patients compared to non-readmitted patients), fluid and electrolyte disease (15% higher), and DM with complications (about 7% higher). The most common diagnosis categories are hypertension (n=704) and hyperlipidemia (n=421). Remaining diagnosis categories of interest did not display an increased incidence among those readmitted (see Table 2).

Assessment of confounding by the 10% gold standard method reveals confounding only by race for models with urban-rural classification, and distance to Emory clinic as predictors. Given race is also significantly different in the chi-squared analysis (Table 1), it was decided that race should be treated as a confounder and adjusted for in all final models. The hazard of 30-day readmission among those with a severe CHD diagnosis is not significantly different from those with a non-severe CHD diagnosis. This result is consistent across all three models (Table 3). There is also no difference found for rates of 30-day readmission between those living in an area classified as 'urban' vs. 'rural' across all three models (Table 3).

Patients with CHF non-hypertensive at the time of index admission have a higher hazard for 30-day readmission, evident in all three models. This association is also found for patients with fluid & electrolyte disease. There is no evidence of an increased hazard for patients with DM with and without complications. The ROCs reveal that a model including all three diagnoses have an area under the curve of 0.58, indicative of moderate prediction of 30-day readmission (see Figure 1). CHF non-hypertensive and fluid & electrolyte disease contribute to a higher predictive value, while DM with and without complications display no increased prediction (Supplementary Figures 1, 2, and 3). There is no difference in the hazard of 30-day readmission for the log transformed distance between a patient zip code and Emory Clinic, the listed NPI address, and the nearest ACHD provider.

Kaplan-Meier curves displayed the three DM categories (DM with complications, DM without complications, and no DM), DM with complications have slightly lower survival probability, meaning the patients in this category experience more readmissions over time than the other two categories. Survival probabilities remain similar for the three DM categories until around day 25 where those with DM with complications have a greater drop in survival

probability than the other two categories. The Kaplan-Meier curve for CHF non-hypertensive displays survival probabilities that diverge between 7-10 days into follow-up time and continue to diverge to the end of follow-up. Similarly, for the Kaplan-Meier curve analyzing fluid & electrolyte disease, the survival probabilities diverge around 7-10 days and continues through the end of follow-up. Race also displays divergence in the Kaplan-Meier curve from around 12 days onwards.

Discussion

We found several factors associated with 30-day hospital readmission rates among ACHD patients with Medicaid coverage in Georgia. Those include diagnoses at index admission of CHF non-hypertensive, fluid & electrolyte disease, DM with complications and black race. We found no significant associations with 30-day hospital readmission rates by CHD severity, age, or distances from patient zip code to Emory Clinic, a nearest ACHD provider.

CHF is the leading cause of hospitalization and healthcare costs in the United States [18]. Patients with CHF non-hypertensive are likely to be readmitted at higher rates due to CHF's complex medical pathology. Various factors contribute to the acute exacerbation of chronic CHF including poor medication and diet compliance [22]. Poor diet or medication compliance also contribute to uncontrolled DM, typically due to lack of glycemic control.

CHF leads to decreased cardiac output which can then decrease renal perfusion resulting in renal dysfunction and electrolyte imbalance [40]. Diuretic medications, a treatment for congestive heart failure, also can trigger electrolyte imbalance [41]. While other studies have reported an increase in 30-day hospital readmissions among ACHD patients with CHF at index admission [21] [22], they did not report increased readmissions for patients with DM or fluid &

electrolyte disease at index admission. Physicians and hospital systems currently target CHF patients for reducing readmission rates. Examples include: hospital initiatives using home-visiting programs, multidisciplinary heart failure clinic interventions, and structured telephone support [18]. Our study helps with identifying risk groups, within the broader ACHD population, that can possibly be targeted for reducing readmission.

We did not find CHD severity to be associated with increased readmissions, unlike other investigators [21]. The discrepant findings are possibly due to the severity classification schemes used. The Marelli scheme classifies severe CHD as lesions with the highest probability for cyanosis or surgical intervention early in life [6]. There may be better way to classify these lesions based on patient outcomes.

To our knowledge, no other study assesses travel distances in association with 30-day readmissions among an ACHD population. Other travel distance studies analyzing the general population have found longer travel distances are associated with increased 30-day readmission rates, attributing findings to poor healthcare access, especially for follow-up [26]. If patients were found not to follow-up within 7 days after index hospitalization discharge, their likelihood for being readmitted increased [26]. This was evident in our Kaplan-Meier curves analyzing CHF, fluid & electrolyte disease, and race (supplemental Figures 4, 5, and 6). Curves representing patients with these exposures diverged from those without about 7-12 days post-index admission discharge. These findings indicate that about 7-10 days may be an optimal time to follow-up in the outpatient setting after discharge.

Strengths and Limitations

Strengths of the study include having a large sample size. However, Medicaid claims data quality limit our analysis, with substantial underreporting of race and possible inaccurate

diagnosis codes. The diagnoses codes used may include more diagnoses and procedures associated with potential higher billing and may not accurately reflecting the patients' condition. The population eligible for Medicaid is also dependent on income and does not represent Medicare and private insurance patients. Therefore, results may lack generalizability to the entirety of the ACHD population. The distance calculated for patients' travel distance to specialized cardiology facilities was created using zip codes, not exact addresses; thus, distances were rough estimates. The listed NPI addresses may also not be accurately reflecting the address from where the service was provided. Lack of information on smoking status and other potential confounding factors may have introduced unmeasured bias.

Conclusion

Specific comorbid diagnoses at index admission and black race identify subpopulations at increased risk for more likely 30-day hospital readmission. Increased attention to comorbid diagnoses during initial hospital stay may reduce 30-day hospital readmission rates and improve health outcomes for the ACHD population.

CHAPTER IV: EXTENDED ANALYSIS

Characteristics of the Cohort

The final analytic dataset included a cohort of 1,697 patients, 365 of whom experienced a subsequent admission within 30 days. The only predictor from Table 1 associated with 30-day readmission is race with a significantly higher proportion of black patients having a readmission within 30 days compared to white patients. There are 13 Asian patients initially included for analyses (6 with a readmission and 7 without); however, we decided to exclude these individuals due to low cell counts. CHD severity, age, and sex are not significantly different between patients with a 30-day readmission and those without.

Diagnosis Categories at Readmission

A separate descriptive analysis compares the diagnoses at index readmission and diagnoses at readmission among those who were readmitted (see supplementary Table 1). No significant differences are found among the top 13 comorbid diagnosis categories by incidence within the population.

Proportional Hazards Assumption

The proportional hazards (PH) assumption tests race, age, sex, CHD severity, and diagnosis categories at index admission including CHF non-hypertensive, DM with and without complications, and fluid & electrolyte disease. The PH assumption is first tested using log(-log(survival)) survival curves. The log(-log(survival)) survival curves do not show any significant evidence that the hazard in the exposed is different from the unexposed over time (Supplementary Figures 13-19). A goodness of fit test was then conducted for predictors. Schoenfeld residuals are obtained from the Cox-Proportional model and ranks are given to the patients with 30-day readmissions in the order from which they occurred (days since index

admission). Correlation assessment using SAS Proc Corr, analyzes the association between the Schoenfeld residual and the rank variable. The resulting p-values for each predictor are > 0.05 . Lastly, time-dependent variables are created for each covariate using the time distributions $g(t) = t$ and $g(t) = \ln(t)$. Each predictor is inserted into a Cox-Proportional model separately for each time distribution. The chi-square test statistic and resulting p-values are >0.05 . Results from these analyses indicate the PH assumption is met for all predictors.

Distance Analyses

Distance from patient zip code to Emory Clinic is calculated using straight line latitude-longitude coordinates, including patients with listed zip codes outside the state of Georgia. The mean distance was 86.2 miles, standard deviation 86.3 miles, min 2.11 miles and a max of 1,938 miles. Distance from patient zip code to the closest ACHD provider is similarly calculated and resulted in a mean of 38.8 miles, standard deviation of 32.6, min of 0.25 and max 125.7. Lastly, distance from patient zip code to the listed NPI address is calculated and found to have a mean of 27.6 miles, standard deviation of 78.5, min of 0 and max of 1,980. Because of the extremely high variance in the resulting distributions, we log transformed the distance measures. After log transformation, the distribution results are as follows:

	Distance to Emory Clinic – Log transform (mile equivalent)	Distance to Nearest ACHD Provider – Log transform (mile equivalent)	Distance to Listed NPI Address – Log transform (mile equivalent)
Mean	4.02 (55.7)	3.20 (24.5)	1.15 (3.2)
Standard Deviation	1.04 (2.83)	1.12 (3.1)	0.41 (1.5)
Min	0.75 (2.12)	-1.39 (0.3)	-9.21 (0)
Max	7.57 (1939.1)	4.91 (135.6)	7.59 (1978.3)
25th Percentile	3.39 (29.7)	2.75 (15.6)	1.81 (6.1)
Medium	4.17 (64.7)	3.37 (29.1)	2.64 (14.0)
75th Percentile	4.88 (131.6)	3.97 (53.0)	3.37 (29.1)

Before log-transformation, a Cox-Proportional model was run on categories of travel distance in miles. The categories were <10 miles, ≥ 10 -20 miles, ≥ 20 -30 miles, and ≥ 30 miles. No significant differences were found in hazard of 30-day readmission except for the unadjusted models comparing those who live more than 30 miles from Emory (HR = 0.78), and an ACHD provider (HR = 0.79). After adjustment in the fully adjusted gold standard model and the final model adjusting for race, these associations were found to be null.

Kaplan-Meier Curves

Kaplan-Meier curves assess the unadjusted association between predictors and time until readmission (Figures 6-12). These predictors include age, race, sex, CHD severity, CHF non-hypertensive, DM with and without complications, and fluid & electrolyte disease. No significant differences between categories are found for age, CHD severity, or sex. Among the three DM categories (DM with complications, DM without complications, and no DM), DM with complications have slightly lower survival probability, meaning the patients in this category experience more readmissions over time than the other two categories. Survival probabilities remain similar for the three DM categories until around day 25 where those with DM with complications have a greater drop in survival probability than the other two categories. The Kaplan-Meier curve for CHF non-hypertensive displays survival probabilities that diverge between 7-10 days into follow-up time and continue to diverge to the end of follow-up. Similarly, for the Kaplan-Meier curve analyzing fluid & electrolyte disease, the survival probabilities diverge around 7-10 days and continues through the end of follow-up. Race also displays divergence in the Kaplan-Meier curve from around 12 days onwards. The similarities between the Kaplan-Meier curves for CHF and fluid & electrolyte disease may be due to physiological ties. In addition, previous literature indicates a predictor for increased readmissions

is not following-up within 1 week of discharge. The timing of the readmissions for patients with CHF, fluid & electrolyte disease, and black patients support this hypothesis as they all tend to be readmitted between 7-10 days after discharge.

CHAPTER V: PUBLIC HEALTH IMPLICATIONS AND FUTURE TRENDS

This study identifies risk factors associated with increased rates of 30-day readmission in an ACHD population. Predictors include black race and diagnosis categories including CHF non-hypertensive, fluid & electrolyte disease, and DM with complications. Physicians and hospital systems currently target CHF patients for reducing readmission rates. Examples include hospital initiatives using home-visiting programs, multidisciplinary HF clinic interventions, and structured telephone support [18]. Our study may help with identifying risk groups, within the broader ACHD population, who can be targeted for reducing readmission.

A major factor that could likely decrease hospital readmission rates is with adequate physician follow-up in the days following discharge from a hospital admission [43]. This study tried to assess if longer travel distances to follow-up care facilities such as the Emory Clinic, the nearest Georgia ACHD provider, or the NPI address listed on the claim, were associated with an increase in readmission rates. There was no statistical evidence to suggest this was the case. However, results may not accurately reflect the travel burden for several reasons. One of which is the facilities used in the study may not be where patients are receiving follow-up care. Future studies would benefit from having robust data on patient follow-up and accurate travel data considering modes of transportation and traffic. Data on outpatient clinic visits post-discharge would be helpful in identifying other risk factors associated with increased readmission.

With the implementation of the Hospital Readmissions Reduction Program (HRRP), reductions in 30-day readmission rates have become a target for quality improvement. Provider incentives outlined in the HRRP are primarily focused on reducing readmission rates which in theory improves the quality of care for the patient and patient outcomes. The current literature has yet to establish a direct link between 30-day hospital readmission and patient outcome

measures [44]. Because of this, there is doubt regarding the use of financial incentives for providers and whether there is any relationship to an increase in quality of care or improvement of patient outcomes [44]. Future research should focus on how 30-day readmission rates are associated with patient outcomes and quality of care.

Racial differences in 30-day readmissions are likely due to many factors influencing the access to care for black populations compared to white. These barriers may include inadequate transportation for follow-up, monetary issues preventing medication dispersal, and cultural barriers that may prevent the consumption of a recommended diet compliant with their disease status. These cultural and social barriers likely lead to more complications associated with the populations chronic disease state. More research detailing specific racial barriers for access to health would give insight for targeted intervention strategies for reducing readmission rates in the black ACHD population.

This study raises further questions when analyzing ACHD populations: Is the Marelli scheme for classifying CHD severity adequate or is there evidence of misclassification? Is travel distance a true barrier for follow-up care in an ACHD population?

- 7.2.8 Conduction disorders [105.] - 105
 - 7.2.8.1 Atrioventricular block - 4260 42610 42611 42612 42613
 - 7.2.8.2 Bundle branch block - 4262 4263 4264 42650 42651 42652 42653 42654
 - 7.2.8.3 Anomalous atrioventricular excitation - 4267
 - 7.2.8.4 Other conduction disorders - 4266 42681 42682 42689 4269 V450 V4500 V4501 V4502 V4509 V533 V5331 V5332 V5339
- 7.2.9 Cardiac dysrhythmias [106.] - 106
 - 7.2.9.1 Paroxysmal supraventricular tachycardia - 4270
 - 7.2.9.2 Paroxysmal ventricular tachycardia - 4271
 - 7.2.9.3 Atrial fibrillation - 42731
 - 7.2.9.4 Atrial flutter - 42732
 - 7.2.9.5 Premature beats - 42760 42761 42769
 - 7.2.9.6 Sinoatrial node dysfunction - 42781
 - 7.2.9.7 Other cardiac dysrhythmias - 4272 42789 4279 7850 7851

- 7.2.10 Cardiac arrest and ventricular fibrillation [107.] - 42741 42742 4275
- 7.2.11 Congestive heart failure; nonhypertensive [108.] - 42820 42821 42822 42823 42830 42831 42832 42833 42840 42841 42842 42843
 - 7.2.11.1 Congestive heart failure - 4280
 - 7.2.11.2 Heart failure - 39891 4281 4289
- 7.3 Cerebrovascular disease - 109 110 111 112 113
 - 7.3.1 Acute cerebrovascular disease [109.] - 109
 - 7.3.1.1 Intracranial hemorrhage - 430 431 4320 4321 4329
 - 7.3.1.2 Occlusion of cerebral arteries - 43301 43311 43321 43331 43381 43391 4340 43400 43401 4341 43410 43411 4349 43490 43491
 - 7.3.1.3 Acute but ill-defined cerebrovascular accident - 34660 34661 34662 34663 436
 - 7.3.2 Occlusion or stenosis of precerebral arteries [110.] - 4330 43300 4331 43310 4332 43320 4333 43330 4338 43380 4339 43390
 - 7.3.3 Other and ill-defined cerebrovascular disease [111.] - 4370 4371 4373 4374 4375 4376 4377 4378 4379
 - 7.3.4 Transient cerebral ischemia [112.] - 4350 4351 4352 4353 4358 4359
 - 7.3.5 Late effects of cerebrovascular disease [113.] - 438 4380 43810 43811 43812 43813 43814 43819 43820 43821 43822 43830 43831 43832 43840 43841 43842 43850 43851 43852 43853 4386 4387 43881 43882 43883 43884 43885 43889 4389
- 7.4 Diseases of arteries; arterioles; and capillaries - 114 115 116 117
 - 7.4.1 Peripheral and visceral atherosclerosis [114.] - 114
 - 7.4.1.1 Atherosclerosis of arteries of extremities - 4402 44020 44021 44022 44023 44029 4404
 - 7.4.1.2 Peripheral vascular disease unspecified - 4439
 - 7.4.1.3 Other peripheral and visceral atherosclerosis - 4400 4401 4408 4409 5570 5571 5579
 - 7.4.2 Aortic; peripheral; and visceral artery aneurysms [115.] - 44321 44322 44323 44324 44329

- 7.4.2.1 Abdominal aortic aneurysm; without rupture - 4414 44772
- 7.4.2.2 Other aneurysm - 4410 44100 44101 44102 44103 4411 4412 4413 4415 4416 4417 4419 4420 4421 4422 4423 44281 44282 44283 44284 44289 4429 44770 44771 44773
- 7.4.3 Aortic and peripheral arterial embolism or thrombosis [116.] - 44501 44502 44581 44589
 - 7.4.3.1 Arterial embolism and thrombosis of lower extremity artery - 44422
 - 7.4.3.2 Other arterial embolism and thrombosis - 4440 44401 44409 4441 44421 44481 44489 4449
- 7.4.4 Other circulatory disease [117.] - 117
 - 7.4.4.1 Hypotension - 4580 4581 4588 4589
 - 7.4.4.2 Other and unspecified circulatory disease - 4430 4431 44381 44382 44389 4460 4461 4462 44620 44621 44629 4463 4464 4465 4466 4467 4470 4471 4472 4473 4474 4475 4476 4478 4479 4480 4481 4489 4590 45989 4599 7859 79430 79431 79439 7962 V125 V1250 V1253 V1254 V1259 V151 V421 V432 V4321 V4322 V434 V717
- 7.5 Diseases of veins and lymphatics - 118 119 120 121
 - 7.5.1 Phlebitis; thrombophlebitis and thromboembolism [118.] - 118
 - 7.5.1.1 Phlebitis and thrombophlebitis - 4510 45111 45119 4512 45181 45182 45183 45184 45189 4519 V1252
 - 7.5.1.2 Other venous embolism and thrombosis - 452 4530 4531 4532 4533 45340 45341 45342 45350 45351 45352 4536 45371 45372 45373 45374 45375 45376 45377 45379 4538 45381 45382 45383 45384 45385 45386 45387 45389 4539 V1251
 - 7.5.2 Varicose veins of lower extremity [119.] 4540 4541 4542 4548 4549
 - 7.5.3 Hemorrhoids [120.] - 4550 4551 4552 4553 4554 4555 4556 4557 4558 4559
 - 7.5.4 Other diseases of veins and lymphatics [121.] - 4563 4564 4565 4566 4568 4570 4571 4572 4578 4579 4591 45910 45911 45912 45913 45919 4592 45930 45931 45932 45933 45939 45981

Appendix E: ICD-9-CM Codes and Corresponding CCS Multilevel Classification (All Levels)

11.4 Indications for care in pregnancy; labor; and delivery 190 191	187 188 189
11.4.1 Malposition; malpresentation [187.]	187
11.4.1.1 Breech presentation	-
65220 65221 65223	
11.4.1.2 Other malposition; malpresentation	-
65200 65201 65203 65210 65211 65213 65230 65231 65233 65240 65241 65243 65250 65251 65253 65260 65261 65263 65270 65271 65273 65280 65281 65283 65290 65291 65293 66000 66001 66003	
11.4.2 Fetopelvic disproportion; obstruction [188.]	188
11.4.2.1 Fetopelvic disproportion	-
65340 65341 65343	
11.4.2.2 Other disproportion or obstruction	-
65300 65301 65303 65310 65311 65313 65320 65321 65323 65330 65331 65333 65350 65351 65353 65360 65361 65363 65370 65371 65373 65380 65381 65383 65390 65391 65393 66010 66011 66013 66020 66021 66023 66030 66031 66033 66040 66041 66043 66050 66051 66053 66060 66061 66063 66070 66071 66073 66080 66081 66083 66090 66091 66093 67810 67811 67813	
11.4.3 Previous cesarean section [189.]	-

65420 65421 65423		
11.4.4 Fetal distress and abnormal forces of labor [190.]		190
11.4.4.1 Fetal distress	-	
65630 65631 65633		
11.4.4.2 Uterine inertia	-	
66100 66101 66103 66110 66111 66113 66120 66121 66123		
11.4.4.3 Precipitate labor	-	
66130 66131 66133		
11.4.4.4 Other abnormal forces of labor	-	
66140 66141 66143 66190 66191 66193 66200 66201 66203 66210 66211 66213 66220 66221 66223 66230 66231 66233		
11.4.5 Polyhydramnios and other problems of amniotic cavity [191.]		191
11.4.5.1 Premature rupture of membranes	-	
65810 65811 65813		
11.4.5.2 Infection of amniotic cavity	-	
65840 65841 65843		
11.4.5.3 Other problems of amniotic cavity	-	
65700 65701 65703 65800 65801 65803 65820 65821 65823 65830 65831 65833 65880 65881 65883 65890 65891 65893 7923		
11.5 Complications during labor		192 193 194
11.5.1 Umbilical cord complication [192.]		192
11.5.1.1 Cord around neck with compression	-	

66310 66311 66313		
11.5.1.2 Other and unspecified cord entanglement with or without compression	-	
66320 66321 66323 66330 66331 66333		
11.5.1.3 Other umbilical cord complications	-	
66300 66301 66303 66340 66341 66343 66350 66351 66353 66360 66361 66363 66380 66381 66383 66390 66391 66393		
11.5.2 Trauma to perineum and vulva [193.]		193
11.5.2.1 First degree perineal laceration	-	
66400 66401 66404		
11.5.2.2 Second degree perineal laceration	-	
66410 66411 66414 66460 66461 66464		
11.5.2.3 Third degree perineal laceration	-	
66420 66421 66424		
11.5.2.4 Fourth degree perineal laceration	-	
66430 66431 66434		
11.5.2.5 Other perineal laceration and trauma	-	
66440 66441 66444 66450 66451 66454 66480 66481 66484 66490 66491 66494		
11.5.3 Forceps delivery [194.]	-	
66950 66951		
11.6 Other complications of birth; puerperium affecting management of mother [195.]		-
